Why are we concerned about the consumption of the Boreal forest floor?

- Deep layers
- Large pool of biomass (+100 tons/acre)
- Often drives fire behavior
- Potential for large fire effects
 - Smoke emissions (1 ton of PM_{2.5}/acre)
 - Regional haze
 - Permafrost melting
 - Erosion
 - Plant succession

Forest Floor Consumption and Smoke Characterization Project

Objectives

- Quantify fuel consumption of the forest floor in the treated and control plots
- Compare forest floor consumption within the treated versus non-treated plot sites.
- Use fuel consumption data to validate current forest floor consumption model in Consume.

Pre-fire Inventory Methods

- Standard set of protocols to measure forest floor depth, reduction, and consumption.
- 16 permanent plots for each of the control and treated sites
- 16 forest floor pins per plot
- Independent variables measured including moisture content, weather, and density

Forest Floor Moisture Content & Weather

Live Moss

Dead Moss

Upper Duff

Lower Duff

Mineral Soil

**A1 – Thinned
Treatment**

This aerial photograph shows a large forested area with two specific regions highlighted for thinning treatment. The area is characterized by a mix of green coniferous trees and patches of brown, dead or dying trees. A winding road or path is visible on the right side, and a small body of water is in the upper right corner. The two treatment areas are marked with red rectangles: one in the upper right and another in the lower right.

**A2 – Thinned
Treatment**

Post Fire Inventory Results

Forest Floor Reduction

Forest Floor Reduction

Forest Floor Percent Consumption (Pins that burned)

Management Implications

- Lower fuel moistures noted in the upper moss layers of treated site due to increased solar radiation and wind.
- When all pins considered, less forest floor consumption noted in treated site versus control site due to mosaic burn.
- Forest floor consumption models predicted treated and control site consumption reasonably well. These models require forest floor depth and upper forest floor moisture as input variables.
- Forest floor moisture content will need to be measured until a moisture model or instrumentation is developed

Fire Behavior on Nenana Ridge

Objective:

Characterize effect of treatments on Fire Behavior

Bret Butler

Summary

- Quantified energy release across Unit A.
- Improved measurement methods and instruments
- Demonstrated potential value of IR imagery
 - Rate of Spread
 - Interpreting point measurements across time and space
 - Relating fire behavior to fuels.
